Computability and Combinatorics 2023

## Outline

## $R C A_{0}^{*}$

Cardinality

Ordinals

Comparing ordinals

Ordinal suprema - uniqueness

Ordinal suprema - existence

## Context

Reverse Mathematics: Calibrate logical strength of theorems by set-theoretic existence axioms.
Use a first-order theory of second-order arithmetic.
$R C A: P^{-}$(finitary part of Peano Arithmetic), induction for all formulas, recursive ( $\Delta_{1}^{0}$ ) comprehension axiom.
$R C A_{0}$ : Weaken induction to $\Sigma_{1}^{0}$ formulas.
$R C A_{0}^{*}$ : Weaken induction to $\Delta_{1}^{0}$ formulas; exponentiation is total.

## Models of $R C A_{0}^{*}$

Factorization of polynomials and $\Sigma_{1}^{0}$ induction
Stephen G. Simpson and Rick L. Smith
1986
Annals of Pure and Applied Logic

A model $M$ of $\mathrm{RCA}_{0}^{*}+\neg / \Sigma_{1}^{0}$ has $\Sigma_{1}^{0}$-definable proper cuts.
I is $\Sigma_{1}^{0}$-definable but not an element of $M$.

$F$ is increasing and cofinal with range $X$.
$F$ and $X$ are elements of $M$.

M

You can also get this picture by starting with:

- An unbounded set $X$ in $M$ to enumerate in order.
- A definition by primitive recursion of an increasing function $F$.

## Cardinality in $R C A_{0}^{*}$

If $I$ is proper, $X$ is a subcountable infinite set.
Cardinals in $M$ : Numbers, proper $\Sigma_{1}^{0}$-definable cuts, $\omega_{M}$. The cardinals are linearly ordered.

Cardinality behaves well with respect to functions between sets, pairwise sums, and pairwise products.

Let $I$ be a $\Sigma_{1}^{0}$-definable cut closed under addition.
(There are many in any model of $R C A_{0}^{*}+\neg / \Sigma_{1}^{0}$.)
$I$ is an (additively) indecomposable cardinal:

$$
(\kappa<I) \&(\lambda<I) \Longrightarrow(\kappa+\lambda<I)
$$

If $\kappa<I$ and $\mu$ is any cardinal,
$(\operatorname{CARD}(A \cup B)=\mu+I) \&(\operatorname{CARD}(A)=\kappa) \Longrightarrow$

$$
\operatorname{CARD}(B)=\mu+I
$$

## Ordinals in $R C A_{0}$

A survey of the reverse mathematics of ordinal arithmetic
Jeffry L. Hirst
2005

Reverse Mathematics 2001 ed. S. G. Simpson

A linear ordering $\langle X, \leq x\rangle$ is ill-founded iff there is (equivalently):

- A nonempty $Y \subseteq X$ with no $\leq x$-least element.
- A $\Sigma_{1}^{0}$-definable cut $I$ with a decreasing function $F: I \rightarrow X$.

An ordinal is a well-founded linear ordering $\left\langle\alpha, \leq_{\alpha}\right\rangle$.
The ordinals are closed under pairwise addition.

For any $\Sigma_{1}^{0}$-definable cut I we have:

The set $X$ with the usual ordering is an ordinal of order type $I$ :

$$
\alpha_{I}=\langle X, \leq\rangle .
$$

If $I$ is closed under addition, $\alpha_{I}$ is (additively) indecomposable.

## Comparing ordinals

For ordinals $\alpha$ and $\beta$ define
$\alpha \leq_{w} \beta$ iff there is an order-preserving embedding $F: \alpha \rightarrow \beta$, $\alpha<{ }_{w} \beta$ iff $\alpha+1 \leq{ }_{w} \beta$.

Theorem ( $R C A_{0}^{*}$ )
For ordinals $\alpha$ and $\beta$,
$\operatorname{CARD}(\alpha)<\operatorname{CARD}(\beta) \Longrightarrow \alpha<_{w} \beta$.

Theorem ( $R C A_{0} ; \mathrm{H}$. Friedman and J. Hirst)
$A T R_{0} \Longleftrightarrow$ all ordinals are $\leq_{w}$-comparable.

Theorem $\left(R C A_{0}^{*}+\neg / \Sigma_{1}^{0}\right)$
There are ordinals $\alpha$ and $\beta$ such that

$$
\alpha \mathbb{Z}_{w} \beta \& \beta \not \mathbb{L}_{w} \alpha .
$$

## Corollary

Friedman and Hirst's theorem holds over the base theory $R C A_{0}^{*}$.

Theorem $\left(R C A_{0}^{*}+\neg / \Sigma_{1}^{0}\right)$
There are ordinals $\alpha$ and $\beta$ such that

$$
\alpha \not \mathbb{Z}_{w} \beta \quad \& \quad \beta \not \leq_{w} \alpha
$$

Proof: Let $I$ be a $\Sigma_{1}^{0}$-definable cut closed under addition, and $b$ a number bounding $l$.

That is, $I<b$ as cardinals.
Define ordinals $\alpha=\alpha_{I}+b$ and $\beta=b+\alpha_{I}$.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not Z_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not Z_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

To show $\alpha \not \mathbb{Z}_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

This is a contradiction.

To show $\alpha \not Z_{w} \beta$, suppose $F: \alpha \rightarrow \beta$ is an embedding.

This is a contradiction.

The proof $\beta \not \mathbb{L}_{w} \alpha$ is similar.

## Ordinal suprema

If $S=\left\langle\beta_{x} \mid x \in \alpha\right\rangle$ is a well-ordered sequence of ordinals, the ordinal $\gamma$ is:

An upper bound for $S$ if $(\forall x \in \alpha)\left(\beta_{x} \leq_{w} \gamma\right)$.
A minimal upper bound for $S$ if $\gamma$ is an upper bound and no proper initial segment of $\gamma$ is an upper bound.

A supremum for $S$ if $\gamma$ is the unique minimal upper bound up to isomorphism.

Theorem ( $R C A_{0}$; J. Hirst)
$A T R_{0}$ iff every well-ordered sequence of ordinals has a supremum.

Show $R C A_{0}^{*}$ suffices as a base theory.
Find a weaker form of "every well-ordered sequence of ordinals has a supremum" that is equivalent to $I \Sigma_{1}^{0}$.

## Fact $\left(R C A_{0}^{*}\right)$

If $\gamma$ is a minimal upper bound for $S=\left\langle\beta_{x} \mid x \in \alpha\right\rangle$, then $\operatorname{CARD}(\gamma)$ is the least cardinal $\kappa$ such that

$$
(\forall x \in \alpha)\left(\operatorname{CARD}\left(\beta_{x}\right) \leq \kappa\right)
$$

Corollary
Suppose $\kappa$ is an infinite cardinal, every $\beta_{x}$ has cardinality less than $\kappa$, and the cardinals $\operatorname{CARD}\left(\beta_{\times}\right)$are unbounded in $\kappa$.
Then $\gamma$ is a minimal upper bound for $S$ iff $\operatorname{CARD}(\gamma)=\kappa$ and every proper initial segment of $\gamma$ has cardinality less than $\kappa$.

Corollary
The ordinal $\gamma$ is a minimal upper bound for $\left\langle n \mid n \in \omega_{M}\right\rangle$ iff $\gamma$ is countable and every proper initial segment of $\gamma$ is subcountable.

Theorem ( $R C A_{0}^{*}$ )
TFAE

1. $A C A_{0}$.
2. Every well-ordered sequence of finite ordinals has a supremum.
3. $\left\langle n \mid n \in \omega_{M}\right\rangle$ has a supremum.

Key to proof: $A C A_{0} \Longleftrightarrow \omega_{M}$ is the unique countable ordinal all of whose proper initial segments are subcountable.

Corollary
The theory $R C A_{0}^{*}$ suffices as the base theory in Hirst's theorem that $A T R_{0}$ holds iff every well-ordered sequence of ordinals has a supremum.

## Theorem ( $R C A_{0}^{*}$ )

TFAE

1. $B \Sigma_{2}^{0}$.
2. Every finite-length sequence of finite ordinals has a supremum.

Key idea for $(2) \Longrightarrow(1)$ : By a result of Hirst, if $B \Sigma_{2}^{0}$ fails there is a coloring of $\omega_{M}$ in finitely many colors such that each color class is finite. $R C A_{0}^{*}$ suffices to prove this.

The sequence of color classes, each ordered via the natural ordering, has multiple minimal upper bounds: $\omega_{M}$, and any other countable ordinal all of whose proper initial segments are subcountable.

## Theorem ( $R C A_{0}^{*}$ )

## TFAE

1. $I \Sigma_{1}^{0}$.
2. Every finite-length sequence of finite ordinals whose sizes have a finite upper bound has a supremum.

Key idea for $(2) \Longrightarrow(1)$ : Suppose $I \Sigma_{1}^{0}$ fails, and let $I$ be a non-minimal indecomposable $\Sigma_{1}^{0}$-definable cut, $F: I \rightarrow \omega_{M}$ be a function in $M$, and a be a number bounding $l$.

Define $S=\left\langle\beta_{k} \mid k<a\right\rangle$ where $\beta_{k}=\{x+m \mid x=F(k) \& m<k\}$ with the natural ordering. The sizes of the $\beta_{k}$ are bounded by $I$, and by $a$.

There are multiple minimal upper bounds for $S$ : $\alpha_{l}$, and $\alpha_{J}+\alpha_{l}$ for any $\Sigma_{1}^{0}$-definable cut $J<I$.

## Existence of minimal upper bounds

Theorem ( $R C A_{0}$; J. Hirst)
$A T R_{0}$ iff every well-ordered sequence of ordinals has a supremum.

This, as well as the preceding theorems, relies on examples of sequences that do not have suprema because they have multiple minimal upper bounds.

Theorem ( $R C A_{0}^{*}$ )
If I $\Sigma_{1}^{0}$ does not hold, there is a (finite) sequence of (subcountable) ordinals with no minimal upper bound.

Proof: Let $/$ be an indecomposable $\Sigma_{1}^{0}$-definable cut, and $b$ and $d$ be numbers bounding $l$.

For $n \leq 2 d$, let $\beta_{n}=n b+\alpha_{I}+(2 d-n) b$, with the natural ordering.

For every $n$ we have $\operatorname{CARD}\left(\beta_{n}\right)=2 d b+I$.
Let $S=\left\langle\beta_{n} \mid n \leq 2 d\right\rangle$.
To show $S$ has no minimal upper bound, suppose $\gamma$ is a minimal upper bound and derive a contradiction.

By an earlier fact, we must have $\operatorname{CARD}(\gamma)=2 d b+I$.

Embed $2 d b$ into $\gamma . \operatorname{CARD}(\gamma)=2 d b+1$.

This divides $\gamma$ into intervals. $b \leq \operatorname{CARD}\left(X_{n}\right) \leq b+I$.
We will show $\operatorname{CARD}\left(X_{n} \cup X_{n+1}\right)=2 b+I$ for $0<n<2 d$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

Embed $n b+\alpha_{I}+(2 d-n) b$ into $\gamma$.

$\operatorname{CARD}\left(X_{n} \cup X_{n+1}\right)=2 b+1$.

Now we have partitioned $\gamma$ into $d$-many intervals, $Y_{k}=X_{2 k-1} \cup X_{2 k}$ for $1 \leq k \leq d$.
$\operatorname{CARD}\left(Y_{k}\right)=2 b+I>2 b+1$.
Let $Z_{k}$ be the least size- $(2 b+1)$ subset of $Y_{k}$, and $Z=\bigcup_{k=1}^{d} Z_{k}$.
$\operatorname{CARD}(Z)=2 d b+b>2 d b+I=\operatorname{CARD}(\gamma)$.
This is a contradiction.

## Question

How strong is this statement?

Every well-ordered sequence of ordinals has a minimal upper bound with respect to $\leq_{w}$.
