Motivation-summary

- Can computable objects define 1-randomness;
- Can 1-randomness be decomposed;
- Skl-random vs 1-random;

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

- What is randomness?
- Randomness \Leftrightarrow "No pattern".
- Strings with some "pattern": 010101010101, 011000111100000111111.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

A (10) + A (10) +

- ► Effective randomness ⇔ No effective pattern.
- Effective pattern: a sequence (V_n ⊆ 2^{<ω} : n ∈ ω) of uniformly c.e. sets (with [V_n] ⊇ [V_{n+1}]) such that m(V_n) ≤ 2⁻ⁿ (known as Martin-Löf test).

Lu Liu Email: g.jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

Definition 1

A real $X \in 2^{\omega}$ is *Martin-Löf random* (also called *1-random*) if no Martin-Löf test $(V_n : n \in \omega)$ succeed on X. i.e., $X \notin \bigcap_n [V_n]$.

- Many definitions of effective randomness turn out to be equivalent (to 1-randomness).
- For example, X is 1-random iff there is no left-c.e. supermartingale M succeeding on X (i.e., lim sup_n M(X ↾ n) < ∞).</p>
- Here a *left-c.e. supermartingale* is a non decreasing computable array $(M[t]: t \in \omega)$ of supermartingales such that $\lim_{t\to\infty} M[t](\sigma) = M(\sigma)$ exists for all $\sigma \in 2^{<\omega}$.

- Unfortunately all definitions of 1-randomness concern c.e.ness, which is dissatisfactory since it is supposed to be an effective randomness notion. Numerous definitions that try not to use c.e.ness are given such as:
 - Schnorr randomness: the reals on which no Schnorr test succeed (a Schnorr test is a Martin-Löf test with m(Vn) being computable);
 - Kurtz randomness: the reals that cannot be contained in any measure 0 effectively closed subset of 2^ω;
 - Computable randomness: the reals on which no computable martingale succeed.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○ ○ ○ ○

But none of them are as strong as 1-randomness (1-randomness implies them but not vice versa).

Is there a complexity notion weaker than left-c.e.ness yet makes the supermartingales (of that complexity) define 1-randomness.

Question 2

Or is there a class of left-c.e. supermartingales whose behaviour is somewhat "predictable" defining 1-randomness.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

Motivation—can 1-randomness be decomposed

- If a left-c.e. supermartingale M : 2^{<ω} → ℝ^{≥0} succeeds on X, is it because of its betting strategy of outcome or its strategy of money allocation;
- Here we say *M* is *i*-sided at $\sigma \in 2^{<\omega}$ iff $M(\sigma i) \ge M(\sigma^{-}(1-i))$.

Question 3 (Kasterman?)

Can we decompose M into M_0 , M_1 (meaning $M_0 + M_1$ succeeds on all reals on which M succeeds) such that M_i is *i*-sided.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

Motivation—KL-randomness vs 1-randomness

Will explain later.

Subclass of left-c.e. supermartingales

2 Main result

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

イロト 不得 トイヨト イヨト

kastergale

- For a computable martingale M, we could know (computably) whether $M(\sigma 1) \ge M(\sigma 0)$.
- For a function p :⊆ 2^{<ω} → 2, we say M is p-sided if for every σ ∈ dom(p), M is p(σ)-sided at σ, and for every σ ∉ dom(p), M is both 0-sided, 1-sided at σ.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

▲ロト ▲周ト ▲ヨト ▲ヨト ニヨー のなべ

kastergale

Definition 5 (kastergale)

For left-c.e. supermartingale *M*, we say *M* is *partially-computably-sided* (known as *kastergale*) iff:

for some partial computable function p, M[t] is p[t]-sided.

i.e., For each $\sigma \in 2^{<\omega}$, M has only one chance to decide its sidedness at σ and before it makes that decision, it has to be both 0, 1-sided at σ .

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

・ロト ・ 同ト ・ ヨト ・ ヨト

muchgale

Definition 6 (muchgale)

A supermartingale M is (I, i)-betting if for every σ such that $|\sigma| \equiv i \mod (I)$, we have $M(\sigma) \ge \max\{M(\sigma 0), M(\sigma 1)\}$. i.e., M does not bet at certain steps. A muchgale is a left-c.e. supermartingale that is (I, i)-betting for some I, i.

Questions and known results

- Kasterman wondered if kastergales define 1-randomness (i.e., whether for every non-1-random real X there is a kastergale succeeding on X) [Downey, 2012];
- Hitchock asked the same question with respect to a subclass of kastergale where the biased proportion M(σi)/M(σ) is Σ₁⁰ function;
- Barmpalias, Fang and Lewis-Pye [Barmpalias et al., 2020] considered single-sided (*p*-sided with *p* ≡ *i* for some *i* ∈ 2) left-c.e. supermartingales whose bias is non decreasing and showed that they do not define 1-randomness.
- Muchnick [Muchnik, 2009] considered (2, i)-betting left-c.e. supermartingales and showed that they do not define 1-randomness.

• □ ▶ • 4 □ ▶ • □ ▶ • □ ▶

Conclusion

Theorem 7 ([Barmpalias and Liu, 2021])

The union of kastergales and muchgales does not define 1-randomness. i.e., there is a non-1-random real X on which no kastergale or muchgale succeed.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

イロト 不得 トイラト イラト 二日

Conclusion

Our analysis shows that

If a reasonable subclass of left-c.e. supermartingales defines 1-randomness, it almost means a single member of that class can do so. (2.1)

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

Formalize (2.1)

- A class of supermartingale-approximations is a set M of supermartingale sequences M[≤ t] = (M[0], · · · , M[t]).
- \mathcal{M} is non decreasing iff: M[t] dominates M[t-1];
- M is scale-closed iff: iff for every M[≤ t] ∈ M, every c > 0, cM[≤ t] ∈ M.
- ▶ We say \mathcal{M} is *subsequence-closed* iff for every $M[\leqslant t] \in \mathcal{M}$, every $t_0 < \cdots < t_{s-1} \leq t$, $(M[t_0], \cdots, M[t_{s-1}]) \in \mathcal{M}$.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

▲ロト ▲周ト ▲ヨト ▲ヨト 三ヨー ぺらぐ

Formalize (2.1)

- We say *M* is *homogeneous* iff, roughly speaking, looking at *M* on a cone [ρ][⊥] is the same as that on [Ø][⊥].
- ► Homogeneous, subsequence-closed, scale-closed, Π⁰₁ class: kastergales; given *I*, {(*I*, *i*)-betting supermartingales : *i* < *I*}; muchgale.
- In (2.1), by reasonable, we mean scale-closed, subsequence-closed, homogeneous and Π⁰₁.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

An *M*-gale is: a ω-sequence *M*[< ω] such that *M*[≤ t] ∈ *M* for all t ∈ ω and lim_{t→∞} *M*[t](σ) exists for all σ ∈ 2^{<ω}.

Lu Liu Email: g.jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

A game

Whether computable \mathcal{M} -gales define 1-randomness \hookrightarrow

Whether Alice (controlling the Martin-Löf test) wins against Baby (controlling members of \mathcal{M}) in the following game.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

A game

The finite version of this game:

Definition 8 ((c, n, k)- \mathcal{M} -game)

At each round $t \in \omega$: Alice: enumerates $\sigma \in 2^n$; Baby: presents $M_j[t]$ (for each j < k) such that: $\sum_j M_j[t](\hat{\sigma}) \ge 1$ for some $\hat{\sigma} \preceq \sigma$ (for all $\sigma \in A[t]$); $M_j[\leqslant t] \in \mathcal{M}$ for all j < k. Alice wins if: $\sum_i M_j[t](\emptyset) \ge c$.

Let A denote the set of σ Alice enumerates when she wins.

▲ロト ▲母 ト ▲ヨト ▲ヨト ヨー ショウ

A game

- ▶ Roughly speaking, if Alice has a winning strategy for (c, n, k)-M-game with an arbitrary small cost m(A), then M does not define 1-randomness.
- ► Let $\mathcal{M} = \bigcup_{I} \mathcal{M}_{I}$ where $\mathcal{M}_{I} \subseteq \mathcal{M}_{I+1}$ is Π_{1}^{0} (uniformly in *I*), non decreasing, scale-closed, subsequence-closed and homogeneous.

Claim 9

If for every $l, k \in \omega, \varepsilon > 0, c < 1$, Alice has a winning strategy for (c, n, k)- \mathcal{M}_l -game (for some n) such that $m(A) \leq \varepsilon$, then computable \mathcal{M} -gales do not define 1-randomness.

Lu Liu Email: g.jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

The constant game

Let $a, \Delta, \delta > 0, n, k \in \omega$:

Definition 10 (constant $(a, \Delta, \delta, n, k)$ - \mathcal{M} -game)

At each round $t \in \omega$:

Alice: $\sigma \in 2^n$,

Baby: $M_j[t]$ such that:

- $\sum_{j} M_{j}[t](\sigma) \geq 1$ (for all $\sigma \in A[t]$);
- $M_j[\leqslant t] \in \mathcal{M}$ for all j < k.
- $\sum_{i} M_{j}[t](\rho) \leq 1 + \delta$ for all $\rho \in 2^{\leq n}$.

Alice wins if:

- ▶ (type-(a)) $1 \sum_j M_j[t](\emptyset) \le (1 m(A[t]))/a$; or
- (type-(b)) for some $\sigma_0, \sigma_1 \in A[t], ||\vec{M}[t](\sigma_0) \vec{M}[t](\sigma_1)||_1 \ge \Delta$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○ ○ ○ ○

constant \mathcal{M} -game vs \mathcal{M} -game

- " $\sum_{j} M_{j}[t](\sigma) \geq 1$ " vs " $\sum_{j} M_{j}[t](\hat{\sigma}) \geq 1$ for some $\hat{\sigma} \preceq \sigma$ ";
- $\sum_{j} M_{j}[t](\rho) \leq 1 + \delta;$
- dynamic winning criterion " $1 \sum_j M_j[t](\emptyset) \le (1 m(A[t]))/a$ " vs " $\sum_j M_j[t](\emptyset) \ge c$ "
- ► for some $\sigma_0, \sigma_1 \in A[t]$, $||\vec{M}[t](\sigma_0) \vec{M}[t](\sigma_1)||_1 \ge \Delta$

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

▲□ ▶ ▲ □ ▶ ▲ □ ▶ □ ● ○ ○ ○

Reduce to constant game

- ▶ Roughly speaking, if Alice could win the constant *M*-game (for k = 1) with m(A) < 1, then she could win the *M*-game (for all k) with an arbitrary small m(A).
- \blacktriangleright Let ${\cal M}$ be non decreasing and homogeneous.

Claim 11

If for every a > 0, there exist $\Delta, \delta > 0$, $n \in \omega$ such that Alice has a winning strategy for the constant $(a, \Delta, \delta, n, 1)$ - \mathcal{M} -game with m(A) < 1, then for every $\varepsilon > 0$, c < 1, $k \in \omega$ there is an n such that Alice has a winning strategy for (c, n, k)- \mathcal{M} -game such that $m(A) \leq \varepsilon$.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

• □ ▶ • 4 □ ▶ • □ ▶ • □ ▶

Reduce to constant game

Proof.

See [Barmpalias and Liu, 2021]. section 2.1-2.2 (dynamic winning criterion), section 2.3 (restricting Baby's action), section 4.2 (type-(b) winning criterion), section 4.3 (reduce to k = 1).

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

イロト 不得下 イヨト イヨト

Reduce to constant game

- For kastergale or (l, i)-betting supermartingale-approximation, it's easy to win the constant game (for k = 1), thus Theorem 7 follows.
- ▶ Winning the constant game (for k = 1) is the only part of the proof where we take advantage of sidedness and (1, i)-betting.

Lu Liu Email: g.jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

▲ロト ▲母 ト ▲ヨト ▲ヨト ヨー ショウ

Completeness phenomenon

- Moreover, if *M* could define 1-randomness, then (for some *a* > 0, for every Δ, δ > 0, every *n* ∈ ω) Alice does not have a winning strategy for the constant (*a*, Δ, δ, *n*, 1)-*M*-game so that *m*(*A*) < 1.</p>
- ► This almost means that a single member of \mathcal{M} (the one Baby used against Alice) could define 1-randomness.
- With that said, this is not a concrete proof of (2.1), but a strong evidence.

イロト イロト イヨト イヨト

A close look at iteration argument

Let $c_i \leq 1, \varepsilon_i \geq 0, n_i \in \omega$ for each i < 2.

Claim 12

If (for each i < 2) Alice has a winning strategy for (c_i, n_i, k) - \mathcal{M} -game such that $m(A) \leq \varepsilon_i$. Then Alice has a winning strategy for $(c_0c_1, n_0 + n_1, k)$ - \mathcal{M} -game such that $m(A) \leq \varepsilon_0 \varepsilon_1$.

Proof.

- In (c₀c₁, n₀ + n₁, k)-M-game, invoke winning strategy of (c₀, n₀, k)-M-game.
- But when the strategy tells you to enumerate ρ ∈ 2^{n₀}, instead of enumerating it, play the winning strategy of (c₁, n₁, k)-M-game at the board [ρ][≤] ∩ 2^{n₀+n₁}.
- Hopefully, the sub-game will forces $\sum_{j < k} M_j(\rho)[t] \ge c_1$.

More efficient winning strategy

For $\mathcal{M} = \{(2, i)\text{-betting supermartingale-approximation}\}$, Alice can win the (c, n, k)- \mathcal{M} -game with a cost $m(A) \approx 1/2$ (for sufficiently large n); moreover, this is optimal:

Lemma 13 ([Barmpalias and Liu, 2022])

- There is a real X with $\dim_H(X) = 1/2$ such that there is no (2, i)-betting left-c.e. supermartingale succeeding on X.
- For every real X with dim_H(X) < 1/2, every i ∈ 2, there is a (2, i)-betting left-c.e. supermartingale succeeding on X;</p>

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○ ○ ○ ○

More efficient winning strategy

Alice can win the (c, n, k)- \mathcal{M} -game (with c = 1, n = 2) with a cost $m(A) \leq \frac{3}{4}$. Thus, let $\dim_P(X)$ denote the *packing dimension* of X, namely $\limsup_n K(X \upharpoonright n)/n$.

Theorem 14 ([Barmpalias and Liu, 2022])

There is a real $X \in 2^{\omega}$ on which no (2, i)-betting left-c.e. supermartingale succeeds for all i < 2 such that $\dim_P(X) \le 1 - \frac{1}{2}\log_2(4/3)$.

Lu Liu Email: g. jiayi.liu@gmail.com (CenSubclasses of effective supermartingales: com New Directions in Computability Theory, Lu

・ロット 御 とう ほう く ほう 二日

Given a subclass $\mathcal M$ of left-c.e. supermartingales and $d\geq$ 0,

Question 15

Is there a real X with $\dim_H(X) \leq d$ (resp. $\dim_P(X) \leq d$) such that there is no member of \mathcal{M} succeeding on X.

Question 16

Is there a winning strategy of Alice on the (c, n, k)-M-game (when n is sufficiently large) such that $m(A) \leq \exp(-O(1)n)$?
